June 25th, 2025

### **Summary:**

In lab 2, we are tasked with designing, simulating, and implementing a 4-to-16 decoder along with an enable input on our Digilent Nexys A7-100T board.

### **Design:**

```
Behavior Level Snippet:
                                                           Gate Level Snippet:
always @(*) begin
                                                           assign Y[0] = E \& \sim A[3] \& \sim A[2] \& \sim A[1] \& \sim A[0];
  Y = 16'b0; // reset all outputs to 0
                                                           assign Y[1] = E & \simA[3] & \simA[2] & \simA[1] & A[0];
  if (E) begin // only decode when enabled
                                                           assign Y[2] = E & \simA[3] & \simA[2] & A[1] & \simA[0];
                                                           assign Y[3] = E \& \sim A[3] \& \sim A[2] \& A[1] \& A[0];
     case (A)
       4'b0000: Y = 16'b0000 0000 0000 0001; //
                                                           assign Y[4] = E \& \sim A[3] \& A[2] \& \sim A[1] \& \sim A[0];
                                                           assign Y[5] = E \& \sim A[3] \& A[2] \& \sim A[1] \& A[0];
output 0
       4'b0001: Y = 16'b0000 0000 0000 0010;
                                                           assign Y[6] = E & \simA[3] & A[2] & A[1] & \simA[0];
                                                           assign Y[7] = E & \simA[3] & A[2] & A[1] & A[0];
       4'b0010: Y = 16'b0000_0000_0000_0100;
       4'b0011: Y = 16'b0000 0000 0000 1000;
                                                           assign Y[8] = E & A[3] & \simA[2] & \simA[1] & \simA[0];
       4'b0100: Y = 16'b0000_0000_0001_0000;
                                                           assign Y[9] = E & A[3] & \simA[2] & \simA[1] & A[0];

       4'b1111: Y = 16'b1000 0000 0000 0000;
     endcase
  end
end
```

### **Simulation:**

#### **Testbench Description:**

The testbench tb\_decoder4x16 is designed to verify the correct functionality of a 4-to-16 line decoder module (decoder4x16\_behav). The decoder takes a 4-bit input A, an enable signal E, and produces a 16-bit one-hot output Y.

- Enable = 1 (Active Phase):
  - When the enable signal E is asserted (E = 1), the testbench iterates through all
     16 possible values of the 4-bit input A (from 0000 to 1111)
  - For each input value, it checks that the decoder output Y produces a one-hot encoding by comparing it to 1 << A</li>
  - If the output does not match, the simulation halts with a failure message;
     otherwise, a success message is displayed.
- Enable = 0 (Disabled Phase):
  - After verifying all valid inputs with the decoder enabled, the testbench disables the decoder by setting E = 0
  - It again iterates over all values of A to ensure that the output Y remains zero regardless of the input
  - o Any non-zero output is treated as an error and flagged.
